## 1. General.

a. Harly in 1943, the Los Alamos Laboratory indicated a need for quantities of crystalline boron of normal isotopic content and crystalline boron enriched in 340 (see Book VIII, Vol. 2). Production of the materials was initially regarded as extremely important and very essential to the overall Manhattan District activity. While necessity for the materials was somewhat modified at a later date, nevertheless, from the beginning the boron project was given the highest priority and every effort was made to assure that production would be as prompt and as efficient as possible. The original requirements included the utmost secrecy and minimum publicity in all phases of the material production. Compliance with the security restrictions caused many of the negotiations to be conducted through oral discussion and thus limited correspondence and records to bare essentials.

b. The desired materials were obtained through: research and development by Columbia University (SAM Laboratories); development and processing by the Norton Company; supply of raw material by the Harshaw Chemical Company; development, design, plant construction and processing by the Standard Oil Company of Indiana; and development and processing by the American Cyanamid Company. Each of the organisations involved and its respective performance will be referred to herein under a separate heading.

Clears & Requir

c. Names of personnel involved in the boron procurement activities may be found in the appendices to this chapter, and in other volumes of the History, to which references will be made hereinafter. Those who were most concerned included the following:

Dr. J. R. Oppenheimer, of Los Alamos Laboratory:

Dr. H. C. Urey and Dr. Martin Kilpatrick, of Columbia University (SAM Laboratories):

Dr. Cyril S. Smith, of the Norton Company;

Mr. E. G. Seubert and Dr. E. W. Thiele, of Standard Oil Company of Indiana;

Maj. Gen. L. R. Groves and Lt.Col. J. R. Ruhoff, of the Manhattan District.

## 2. Columbia University. (Refer to App. A-1.)

- a. In May 1943, the request of the Los Alamos Laboratory, described above, was discussed between representatives of Columbia University and the Madison Square Area. That discussion resulted in arrangements whereby, under Contract W-7405-eng-50, Columbia University was to proceed with the necessary/research and development for the production of 500 to 1000 pounds of crystalline boron of normal isotopic content and 50 kilograms of crystalline boron containing not less than 90% B<sup>10</sup>.
- b. The need for this work had been anticipated by personnel at Columbia and four months earlier (in January 1943), under OSRD Contract O Mar 412, research on the separation of boron isotopes had been started. That research had resulted, in April 1943, in the discovery of a promising method of operation. Such a method of operation was still being investi-

gated when the Madison Square Area arrangements became effective, but the information which had already been obtained was such that development could, and did, proceed with a minimum of delay. The separation procedure, which was proven to be successful by continued investigation and plant operation, was based on a counter-current distillation of a dissociable complex or pelymer.

- c. In addition to the study for separation of boron isotopes,

  Columbia initiated a research program concerned with the reduction of

  boron compounds. It was determined under this program that the reduction

  of boron trichloride by hydrogen on heated rods would produce best re
  sults, and development work for this feature was carried out in co
  operation with the Morton Company.
- d. The separated product obtained by the method developed at Columbia was dimethyl ether-boron trifluoride complex and it was then necessary to undertake research on the conversion of that compound to boron trichloride. A pilot plant was set up at the Columbia laboratories and development work was carried out in cooperation with the American Cyanamid Company.

## 3. The Norton Company.

The Norton Company participated in the boron program under twe different lines of procedures first, through cooperation with Columbia University in developing the method of reducing boron trifluoride; and, second, in producing crystalline boron. These activities are referred to in Appendix A-1 for the reduction of boron trifluoride and in Book VII, Vol. 1, for the production of crystalline boron. That

production applied to material of normal isotopic content and was accomplished under Contract (-7405-eng-292, effective 15 January 1944, at a cost of 353,000 (See Book VII, Vol. 1). Covernment-owned raw material, which had been obtained from the Niagara Smelting Company, was supplied to the Norton Company for their process.

Confirming records and supporting data for the Norton Company participation in the boron project are, of necessity, extremely sketchy, as particular care was exercised to prevent general knowledge of their activity being divulged.

#### 4. The Harshaw Chemical Company.

The Harshaw Chemical Company was selected to supply raw material for the Standard Oil process of the boron project. Contract W-7405-eng-289, effective 15 March 1944, called for a supply of 850 pounds of "synthene" per week for six months, starting 1 May 1944. "Synthene" was the code symbol for boron trifluoride containing not less than 97% of BF3 of as constant purity as possible. Subsequent supplements to the contract increased the quantity of raw material to a total of 92,450 younds, at a total contract price of \$72,770 (see Book VII, Vol. 1).

Raw material delivery was completed 1 March 1946.

#### 5. Standard Oil Company of Indiana.

Then research and development at Columbia University had progressed to a stage which permitted design and construction of a production plant for the separation of boron isotopes, contact was made with the Standard Oil Company of Indiana (App. A-2, 3 & 4). That company indicated its

into Contract (-7413-eng-41. The contract was effective as of 2 Cecember 1943, the contemplated work consisting of the design, erection and operation of a suitable production plant for the separation of boron isotopes. In addition to the above work it was understood that the Standard Cil Company would undertake work directed toward; increasing the certainty of the early success of the proposed project; training of technical and non-technical personnel; and, establishing an adequate security system.

A general history of the contractor's activity in meeting contractual requirements is provided in Appendix A-5. That history of the separation project describes: the work objective; selection of the production contractor; plant design features; initial operation; supplementary plant considerations; and the then future possibilities of the process.

difficulties in obtaining desired construction material (App. A-6), and the inadvertent introduction of mercury into the plant system during the leak test procedure (App. A-5). The latter difficulty was considered to be quite serious in its nature and led to the erroneous conclusion that the initial plant would be unsuitable for production and that replacement would be required. Later on during the contract a corrective measure was discovered and the original plant proved to be operable for production purposes.

During the period of operation, a total of 736 gallons of heavy polymer was produced. Appendix A-7 provides letails of that production in regard to lot quantities, percent of heavy polymer for each lot, etc.

Appendix A-7 also includes breakdown figures for the total cost, under Contract W-7418-eng-41, of \$2,309.546.88, prior to any adjustment required

On 8 March 1946 the Contractor was directed, except for the economical completion of material then being processed, to cease operation of the facilities, effective 4 February 1946 (App. A-8). Supplemental Agreement No. 5, of contract N-7418-eng-41, provided for the period of preduction performance to end at 11:59 P.N. on 30 June 1946. Also, in accordance with that supplemental agreement, the contractor placed the process equipment in stand-by condition and stored such equipment as was directed by the contracting officer.

## 6. American Cyanamid Company.

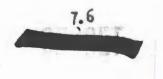

by final audit.

Contract %-7401-eng-91, dated 8 February 1944, with the American Cyanamid Company, required the contractor to process product 890 A to the final product 891 A. Products 890 A and 891 A were the respective code symbols for boron trifluoride dimethyl ether complex and for compatalline boron 10, 98% assay.

The process used in converting the complex to boron was developed under Columbia Contract W-7405-eng-50 (see App. A-1), but the engineering and design work necessary to put the laboratory process on a plant scale was done by the American Cyanamid Company.

It has been mentioned that the initial requirement was the continued production of B<sup>10</sup> until a quantity of 50 kilograms had been completed.

The production schedule called for 1 kilogram of boron as early as possible, a total of 5 kilograms by 15 September 1944, and 5 additional

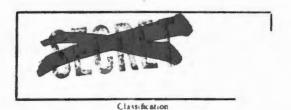

kilograms every month thereafter until the total of 50 kilograms had been obtained. The startup of the plant was, of course, dependent upon the production of separated complex from the Standard Oil Company of Indiana. The rate of production of the separated complex had been established, by the Chicago Area and the Standard Cil Company, to be 5 gallons every three days. The plant of the American Cyanamid Company was designed to run at twice this rate if necessary, since the Chicago Area had intimated that they might be able to arrange for an increase in the rate of separation. The American Cyanamid Company plant had undergone test runs and was ready to operate by 7 July 1944. Unfortunately, material was not available at that time from the Standard Oil Company. While awaiting material from the Standard Oil Company, work continued at the American Cyanamid Company, to improve their process and to prevent possible losses of material. Upon the start of delivery of the 890 A complex from the Standard Oil Company, the American Cyanamid facilities were in readiness and processing to the final product began.

In accordance with supplementary requirements for contract W-7401eng-91, production at the American Cyanamid Company continued well into
1946, and 504 pounds of crystalline boron 10, 850 pounds of calcium
fluoride-boron trifluoride complex, containing a greater than normal ratio
of the 810 isotope, and 242 pounds of calcium fluoride-boron trifluoride
complex, containing a greater than normal ratio of B11, was obtained
(see Book VII, Vol. 1).

The Separation of the Boren Isotopes and the Production of Letalbic Boron

Final Report Submitted in Accordance with the Terms of Contract W-7405, eng-50

Harold C. Urey

July 31,1945

#### I. Historical Review

In May, 1943, the U.S. En incor Corps of the War Department requested that the necessary research work be undertalen to determine methods for the production of crystalline oron. In addition to some 500 to 1,000 pounds of crystalline boron of normal isotopic content, a need was indicated for 50 kilograms of crystalline boron containing not less than 90% of BlO. Fortunately, the need for this naterial had been partly anticipated at Columbia University, and research had sen started in January, 1943, on the separation of the boron isotopus, under 0.3.R.D. Contract Offer Sr 412. In April, 1943, a promising other had seen discovered at Columbia, and was under investigation.

A pilot plant has set up to accumulate enjincering data necessary for the design of a plant which would separate 300 grams of 310 per day. In addition, a research proteam as initiated to study various bethods of reducing boron compounds. After a survey, experimental torsion the reduction of boron trickloside by hydrogen and of boron trickloside by sedium, has carried out. The net od finally chosen was the reduction of boron trickloride by hydrogen on heated rods, and the development work has carried out in cooperation with the Perton Company. The was of this method involved the production of boron trickloride of high purity. The Miagara shalting Company undertook this corb and profuced sufficient trickloride for the production of the required amount of crystalline boron. This orb has considered by the Norton Company by the end of Tay, 1944.

In the meantine, the pilot plane corb on the separation had progressed to a stage where the construction of a plant could be unortal on, and in November, 1943, the design, construction and operation of a plant cast add the responsibility of the Stundard Cil Company of Indiana. As the separated product was to be directly other-boron trifluoride complex, (Cil) 0°F, it was necessary to undertake research on the conversion of this compound to boron trichloride before reduction with hydrogen. In addition, further research work has necessary to add refinements to the reduction step. A pilot plant was set up at the Columbia laboratories, and the development work was carried out with the American Granamid Company. This company began work in February, 1944.

After some delay due to operational difficulties and accidental introduction of percurv into the plant, production of separated boron as the distributed ether-boron trifluoride to plant began in Japany, 1945, and was completed in try, 1945. The appricant Granamid Co. pany plant completed the production of crystalline we lust of specified purity in June, 1945. Experimental surples of Bill were proposed in the pilot plant at Colubba.

It was found that inst part in hading boron, could be separated by a counter-current distillation of a dissociable applies a polymer. This novel enthod of separating isotopes was a stall for the boron instepes and found to be successful, with an overall owe-step officiency sufficiently large to make the method very attractive from both an engineering and purely scientific point of view. This new method of scharation is quite assemble, and is not limited in any way to the boron in topes.

This record is the engineer to the large scale reparation of the boron it topes. The plant is spine to discrepantly emplex (CH3)20. HF3, which has a simple process fractionative for most isolated 0.002. In order to make this method of a parating the term last pus of practical importance, it was necessary to find a method of recovering quantitatively the FF3 from the complex, and this was done. The was on a laboratory case is described in the reports, as well as the large scale in velocity and application to a symmostical scale.

  - b. Reclivery of B from tentalum rols

The research is no in this phase of the work concurred the lot of prent of and a for the production of crystalline boron of high purity and with nearly

100UR=934 File 180 Page 7 7-31-45

complete conversion of the starting boron compound to boron metal. An initial examination of known reactions for the projection of boron disclosed that of them all, the reaction  $\mathbb{E}X_3 + \frac{3}{2} \mathbb{H}_{2} \to \mathbb{F} + 3\mathbb{E}X$ , there X is F, 31, 3r or I, would be expected to

give the purest product because of the volatility of all reactants and products excepting boron.

The equilibrium constants for the reduction of BF3 and BCl3 with H2 were computed approximately from data available in the literature. The computational results confirmed our experimental studies which showed that BF3 was not and BCl3 was reduced by  $\rm H_2$  on, or in the neighborhood of, a surface at 1,300 to 1,500° K. The computations gave for the equilibrium constants at 1,500° K. for BF3 and BCl3,  $\rm 2.4 \times 10^{-11}$  and  $\rm 1.3 \times 10^{-4}$  respectively. The reduction of BBr3 with  $\rm H_2$  was found to occur as easily as that of BCl3, but the brownide was less readily available.

Experimental investigations showed that under proper conditions the beron produced by reduction of BCl<sub>3</sub> with H<sub>2</sub> is crystalline and of greater than 99 atom per cent purity. Also it was shown that the unreduced BCl<sub>3</sub> (the yields were always less than 80 per cent) and the B combined with the het surface could always be recovered as BCl<sub>3</sub> and reused, resulting in very small loss of B. Apparatus was devised for the commercial production of 600 grams or more of B per day. A pilot plant for carrying out this process was a natructed and operated.

The experimental work was carried out under the direction of M. Kilpatrick and C. A. Hutchison, by J. S. Smith, R. S. Schwartz, E. Kalichman, J. L. Thomas, and R. Reider.

## D. An investigation of alternate methods for reduction of borum compounds

- 1. The preparation of boron by the reduction of boron trifluoride with sodium.
  - n. The batch sidium method and carly experiments
  - b. Noth ds involving the simultaneous introduction of sodium and transtiflueride
- 2. The proparation of boron by the reduction of sodium fluoborate with a lium.
- 3. Extraction of sedium fluoride by water from the reaction products
- 4. Preparation of boron by the reduction of boron trifluoride and sodium fluoborate with aluminum
- 5. Preparation of boron by the reduction of boric anhydride with active metals
- 6. The high temperature purification and consolidation of amorphous boron

It was the object of this research program to develop a chemical method for the production of boron of high purity. Initially, the objective was to produce boron either amorphous or otherwise of at least 95 atom per cent purity. Later this was revised to consolidated or crystalline boron of 99 per cent purity. We was directed toward achieving this goal by two methods: (1) A two-stage process

100UR-934 File 180 Page 8 7-31-45

wherein amorphous boron was first prepared by some simple, direct chomical method that was then followed by a purification and/or consolidation treatment at a high temperature. (2) A single-stage process wherein crystalling boron or consolidated boron of high purity was prepared directly by the interaction of free-sedium with boron trifluoride at high temperature.

Primary emphasis was placed on the technique of proparing boron rather than on the comprehensive study of the purity of the products obtained or their recovery. This was particularly evident in cases involving the use of sodium, where the handling of the materials and the type of equipment used proved to be the greatest problem.

This investigation did not yield suitable positive results. The difficulties encountered with equipment and handling of materials presented obstacles that would have necessitated a long-term research.

This work was done under the general direction of M. Kilpatrick, J. S. Spevack and A. Kurts, assisted by H. H. Starke, T. Clarke, G. Cohen, S. Federman, M. Hanig, M. Tetenbaum and R. Ullman.

### III. Analytical Methods

### A. Spectrometric Analysis

A heavy metal mass spectremeter was used for the first work on the isotopic analysis. This instrument was used to get the necessary fundamental results from which a more simple satisfactory routine machine could be designed.

After the basic analysis method had been found, a special instrument was constructed which was then used for routine analysis of B<sup>10</sup> and B<sup>11</sup> compositions. Following the completion of this instrument, a second machine for routine plant control was found necessary and constructed accordingly.

This work was under the general direction of M. G. Inghram and J. S. Smith, assisted by T. G. Schweb, C. Y. Barthel new and H. Groonberg.

#### B. Chemical Analysis

Investigations were carried out on the following subjects:

- 1. Analysis f pure crystalline beren
- 2. Determination of silican and iron in Boron
- 3. Analysis of bran trichlorido
- 4. Analysis of b ron fluoride-mothyl ather complex
- 5. Constituent analysis of boron fluoride-methyl ether complex
- 6. Analysis of exit gases from boren trichleride reduction
- 7. Analysis of constituents and impurities in boron trichlorid
- 8. Complete analysis of borun

The general analytical problems of this project were investigated by a grup composed from M. Judson, C. D. Turner, G. H. Turner, A. J. Flynn, J. A. Vonn, A. D. Kirshenbaum and M. Kurpka.

## INITIAL REPORT - CONTRACT NO. F-7418-eng-41 December 2, 1943

1453

On November 19, 1943, the Standard Oil Company (Indiana) was approached by Brig. Gen. L. R. Groves of the U. S. Army Corps of Engineers as to its willingness to undertake the manufacture of a small amount of a critical chemical. On November 22, 1943 Dr. E. '. Thiele of the Standard Oil Company visited the Madison Square Area Office of the Manhattan District to discuss the technical aspects of the proposed project. By letter of November 24, 1943 from Mr. E. G. Seubert to Gen. Groves, Standard Oil Company indicated its greement to proceed with the design, construction and operation of the necessary facilities, provided a suitable contract were developed to provide for the reimbursement of the cost of construction and operation of the facilities. On December 2, 1943, the U. S. Engineers Office issued a letter of intent covering the proposed project and on December 6, 1943 this letter of intent was accepted by Standard. Subsequently, on January 5, 1944 the parties entered into Contract No. 7418-eng-41 dated December 2, 1943, covering the project.

The objective of the project is the erection and operation of facilities to produce "B" units per day of "X" product (letters "B" and "X" are defined in the "Secret letter" dated December 2, 1943), Hereinafter and in subsequent reports "B" will be considered to be 1.7 gallons (U.S.) and "X" will be called "Heavy Polymer." Heavy polymer is to be fractionated from "Polymer" which is produced by the reaction of "Synthans" with "Monomer."

The steps contemplated for the execution of the contract obligations and the originally expected completion dates for each step are indicated in the following tabulation:

Step	Description	Scheduled Completion Date
1.	Design of Pilot Plant Facilities	Feb. 1, 1944
2.	Preparation of Pilot Plant Site and Installation of Offices and Laboratory	March 1, 1944
3.	Erection of Pilot Plant Facilities	April 30, 1944
4.	Start up of Pilot Plant, Establishment of Equilibrium, and Production of Initial Product	June 2, 1944
5.	Operation of Facilities	*** *** *** *** ***

~ ~ ~

It is to be understood that the above schedule is contingent upon Standard's obtaining delivery at the necessary times of materials and supplies. It is also to be understood that Standard does not guarantee that production of heavy polymer can be started by the indicated date (June 2, 1944); however, Standard will use its best efforts to do so.

In addition to the above work necessary to the execution of the Contract, Standard expects to undertake work directed towards increasing the certainty of the early success of the proposed project. Items of major importance in this category follow:

- 1. Investigation of performance of high afficiency fractionation columns, particularly Stedman columns.
- 2. Investigation of the properties of polymer including:
  - a. Relative volatility of light and heavy polymer
  - b. Corrosion
  - c. Decomposition
  - d. Inflammability
  - e. Toxicity
- 3. Training of technical personnel
- 4. Training of non-technical personnel
- 5. Establishment of an adequate security system from the standpoints of fire protection, espionage, and sabotage.

Work on the above items is of a continuing nature and no schedule is being established in advance.

/s/ J. K. Roberts J. K. ROBERTS

IDM CGD-1

4 January 1944

Memorandum To: The Files.

Subject: Contract No. W-7418 eng-41 with the Standard Oil Company of Indiana.

- 1. The work being undertaken is the separation of isotope Boron 10 from Boron 11. The light component is desired at 95% purity. Boron tri-fluoride will be the basic material. This can be procured as a component. Boron tri-fluoride and methyl other will form a complex which boils at about 200°C. It has been determined that the light complex has a different vapor pressure than the heavy complex and will boil off at a slightly lower temperature. It is believed that the separation can be obtained by distillation. The job is very difficult, however, because the difference of volatility is about one part in a thousand. It is contemplated that fractionating equipment consisting of about a thousand theoretical plates will be used and that the equipment would operate at about a thousand to one reflux ratios. Boron tri-fluoride and methyl ether are both gases but the complex is liquid. The equipment as contemplated will consist of nine columns 35 feet high. The first three will consist of thirteen 6" triangles, the second three of five 6" triangles, and third three of 6" diameter tubes. The chemical engineering job concerned is to get the holdup as low as possible and also prevent decomposition of the complex. This latter will not only ruin production but also cause corrosion of the distillating columns. To decrease corrosion, monel packing will be used. The components will be delivered as gases and it is expected that these will be formed in the complex at the site. This scheme has been worked out at Columbia and no difficulty is expected in effecting the formation of the complex.
- 2. The basic work for this method of separating boron isotopes has presumably been done at Columbia. Drs. Urey and Kilpatrick are the contacts for the Standard Oil people. Technical information for the start of design has been obtained in New York by Dr. Thiele and Mr. Conn from Ruhoff, Kilpatrick, and Urey.
- 3. Specifications call for the production of 1.7 gallons per day of complex 95% pure. This will produce in the order of 600 grams per day of the desired component. It is planned that the plant will be completed by 30 April and that the start up of operations will be 2 June 1944.
- 4. Standard Oil will operate under a prime contract calling for the design construction and operation of the pilot plant built to effect this

Subject: Contract No. W-7418 eng-41 with the Standard Oil Company of Indiana.

separation. Standard Oil is in the process of subcontracting the purchase or fabrication of the equipment and erection of the entire plant to the Foster-Theeler Company. This Company has had experience in the fabrication of Stedman columns which will be used in the pilot plant.

5. At the present moment, the work is organized along the following lines:

E. G. Seubert - President - Standard Oil Company (Ind.) J. K. Roberts, Director of Research R. C. Gunnes, Project Supervisor Arthur H. Conn - Operations Supervisor Technical Men (about 7) Operators, etc (about 25) James Mather - Job Engineer E. W. Thiele - Project Consultant Wm. L. Webb - Administrative Assistant Direct contact with job above this line Indirect contact below M. G. Paulus - Vice President - Manufacturing S. A. Montgomery - Manager Thiting Refinery D. A. Monro - Chief Engineer (acting)

Subject: Contract No. 1-7418-eng-41 with Standard Oil Company of Indiana

7-741?-eng-41 FIDM CGD-4

4th Frapper Ind.

1453

- U. S. Engineer Office, Chicago Area, Chicago, Illineis. 26 October 1945.
  To: The District Engineer, Manhattan District, Oak Ridge, Tennessee Att:
  Captain W. F. Teeter
- 1. The information transmitted herewith is furnished in compliance with 3rd Vrapper Ind. This information has been obtained through personal contact with parties interested in the early history of the contract, principally Drs. H. C. Urey and Martin Kilpatrick, and is not substantiated by documents in the files of the Chicago trea Office. It is suggested that information be requested of the Columbia Area Engineer.
- 2. Dr. H. C. Urey, of Columbis University, was aware of the potential value of the separation of the boron isotopes and undertook a research program to effect such a separation. Dr. Martin Kilpatrick supervised the development program for Dr. Urey. Then sufficient data had been accumulated to indicate the feasibility of such a program, and then a requirement for one of the isotopes had been submitted from Los Alamos, the Fastman Kodak Company of Rochester, New York, a firm engaged in the preparation of fine chemicals, was approached with a request to design, construct, and operate a plant capable of producing the desired fractionation. This concern declined to enter into a contract with the government for this purpose.
- 3. On 19 November 1943, Major General L. R. Groves and Dr. A. H. Compton proposed to Mr. E. G. Subert, President of the Standard Oil Company (Ind.), that his firm undertake an undisclosed project of great importance.
- 4. The Standard Oil Company is a firm with a reputation for competency and efficiency in refinery operations, principal of which is that of precise distillation. Certain members of the research staff, particularly Roberts, Gunness, and Thiele, were well-known to the research organization at Columbia University and were considered by this staff to be particularly capable to engage in such work. Mr. Thiele had been previously employed on the DSM Project on a leave of absence granted by The Standard Oil Company. On 22 November 1943, Mr. Thiele was sent to New York to confer with Messrs. Urey and Kilpatrick, and the nature of the proposed activity was disclosed to the desired separation, and on 24 November 1943, Mr. Subert informed General him. He reported to Mr. Subert that the Standard Oil Company could accomplish Groves that the Standard Oil Company (Ind.) was willing to enter into a contract for such services.
- 5. On 4 December 1943, Major Harold Greenstein presented to the Standard Oil Company (Ind.) a letter-contract dated 2 December 1943. The Chicago Area Office was asked to render administrative services such as priority assistance and certification of deforment requests, for the Standard Oil Company. On 19 January 1944, the Area Engineer, Madison Square Area, transferred

Subject: Contract No. -7418-eng-41 with Standard Oil Company of Indiana

26 October 1945

to the Chicago Area Office, the entire responsibility for the administration of the contract. The original estimate of the cost of the contract was \$300,000, which estimate was raised to \$600,000 prior to the execution of the instrument. The contract was later supplemented to provide additional funds so that the total value of the contract is now \$2,800,000. The contract was negotiated on the basis of cost. The cost is determined as the actual expenditure for this facility, plus operating costs, labor and overhead. The overhead is calculated as 100% of labor, labor being construed to include only operating personnel and not service and maintenance. This calculation is based on the precedent established by a previous contract between the OSRD and the Standard Oil Company (Ind.). The principal item of cost was the design and construction of the facility. This was performed index a subcontract by the Foster Wheeler Corporation of New York, New York. The construction cost is estimated to be \$1,225,000.

For the Area Engineers

T. S. CHAPMAN, Captain, Corps of Engineers, Assistant

#### HISTORY OF

# CONTRACT DA. W-7418 eng-41 CTANDARD DIE COMPANY (INDIANA)

1453

## 1. Objective

Early in the history of the his project, Dr. H. C. brey of Columbia University became aware of the potential value which lay in the fact that the boron isotope of leaser abundance was one of the atoms of present cross section known. Under his direction, a program was undertaken at the SAN Laboratories to devise a method of separation of this boron isotope. The result of the study was that the most feasible method of separation was a fractionation by distillation. The principle under which this fractionation is accomplished is still uncertain but the empirical results obtained with the other complexes of boron trifluroide indicated that a sufficient difference in volutility existed for the successful accomplishment of the separation.

## 2. Selection of Contractor

The Eastman 'odak Company of Rochaster, New York, who have a reputation for the preparation of high-grace chemicals, including a large number which are processed by careful distillation, were tonsidered first as a contractor to design, construct and operate a plant capable of producing the desired fractionation. This company declined to enter into a contract with the government for this purpose.

Since distillation is the foundation of the petroleum refining industry, The Standard Sil Company of Indiana was then approached. The reputation of the Standard Oil Company of Indiana for industry and efficiency in the accomplishment of difficult tasks was well known. Eclimbia University and others were acquainted with the capabilities of certain members of the research staff, particularly Jesses. Roberts, Cunness, and Thiele. Fr. Thiele had been employed previously by the SM.

project on a leave of absonce granted by the Standard oil Company. In 22 sovember 1/43, ar. Thiele was called into conference with Messra. Urey and Milpatrick and the proposed activity was disclosed to him. He agreed that the Standard Oil Company could build a pilot plant which would produce about 600 grams of porth of a concentration of about 75% of the 10 isotope by the method of distillation which had been devised by Orsy and on-workers. Direct negotiation between Major Gameral Groves and Mr. J. K. Roberts of Standard Oil Company resulted in the acceptance by the Standard Cil Company of such a contract (No. 8-7418 eng-41) on 2 December 1943.

Inglneer to perform certain functions with respect to the contractor, namely those related to matters of administration such as auditing disbursements, expediting deliveries of materials and equipment, and processing deferment requests. The Technical direction remained under the Endison Square area until 19 January 1944, when the entire responsibility for the administration of the contract was transferred to the Chicago Area Engineer.

## j. Plant Design

After the nature of the problem was disclosed to the contractor, it was necessary to make a very early docusion with regard to the method and means which would be used to effect a solution. Impediate decisions were necessary with regard to types of equipment required and materials of construction in order that orders might be placed with some nope of obtaining delivery at a date which would permit the construction of the plant and the production of the isotope in coordination with the delivery schedule of products which it was to supplement. Accordingly, other industrial facilities having experience in certain has and pertinent matters of equipment and material were interviewed, and the SAM.

Laboratories were requested to undertable a number of tests in order that sound design decisions might be made as soon as possible. In December 1943, the decision was made to perform the fractionation in a plant consisting of six distillation columns of producted size to operate in cascade. These columns were to be fabricated of monel motal and were to be packed with Stadman packing. Three additional columns were to be erected as stand-by aguingant.

inter a preliminary review of the factors involved in construction, Standard Gil awarded to the Foster necier Corp. a subcontract for the design and construction of the fractionation equipment. This procedure was selected as the most expectations for the rapid construction of the desired facilities. In order that design and construction work on the project could proceed forthwith, the available process information was employed for the prompt est baisament of the process design basis for the prior plant. Simultaneous with the mechanical design and construction of the fractionation unit, Standard and undertaken the development of more analysis information on the process requirements of the project and the performance characteristics of high efficiency fractionation calcans.

## A. Pactors Considered

polymer, would appear to be a relatively simple distillation problem, the operation is complicated by the irreversible decomposition of polymer into liquid and gaseous by-products. This decomposition of the and appreciable extent even at the lowest temperatures union are practical for operation. Furthermore, the large number of theoretical plates required and the low pressure drops permissible lead to the use of entering appreciable actions in series. A careful analysis is required of the factors affecting design in order to possit the selection of the optimum equipment.

The primary factors affecting the process design may be listed as follows:

- a. Helative Volatility, Theoretical Plates and Reflux Hatio
- t. Decomposition
- c. Pressure
- d. Holdup
- e. Number of Columns.

## (1) Relative Volatility

The relative volatility, of the two components being separated has been found to lie in the range of 1.010-1.018, which corresponds to a difference it colling points of only about 0.4 to 018°F. In order to separate two materials boiling so closely together, it is necessary to employ an unusually large number of places and in unusually high reflux ratio. This is illustrated by the following values, calculated for the production by a single column of a bottoms product containing 90% 10 isotope, and an overhead product containing 90% 11 isotope.

u-oriene		Sinimum Plates	Finisus heflux natio
	1.010	518 432	478 415
	1.015	346 289	333 278

The large change in both the minimum plates and minimum reflux ratio for a small change in is to be hoted. It is to be emphasized that the minimum number of plates and the minimum reflux ratio represent limiting values and that the actual number of plates and actual perlux ratios which must be used are considerably greater.

## (2) Decomposition

The irreversible decomposition of polymer into liquid and gaseous by-products is an extremely important factor since the extent of decomposition limits the purity of the product which can be made by

direct fractionation. The extent to which decomposition of heavy polymeroccurs is determined by the decomposition rate (per cent per day) of the colymer and the holdup of heavy polymer within the unit, hence it is important that both factors he kept to a minimum.

The decomposition rate has been found to be a function of the temperature, and hence the distillation pressure. For example, at a temperature of 195°F and a pressure of 150 mm Hg absolute, the decomposition rate is 0.2%/day, while at 220°F and 290 mm, it is 0.6%/day. Although operation of the columns at the lowest obtainable pressure would assure the minimum decomposition rate, the use of such a low pressure would result in large diameter towers and increased holdup in the system. The resultant effect might be an increased extent of decomposition despite a lower decomposition rate.

## (3) Pressure

For the system in question, the available data indicated no effect of pressure on relative volatility, and therefore no effect of pressure upon reflex ratio. Accordingly, with the vapor and reflex duty established by the fractionation requirements of the operation, the received cross sectional area of the column becomes a function of the column pressure. The relationship is such that the required cross sectional area for a given reflex load is approximately preportional to the inverse of the square root of the absolute pressure.

For a given diameter column, the use of a higher pressure will permit a greater reflux capacity which will in turn permit the use of a smaller dumber of plates to achieve a given separation. With a given diameter column containing a given number of plates, increasing the pressure will have possible the production of a higher purity product, or an increased quantity of a given purity product except as decomposition interferes.

In considering the effect of distillation pressure on the design and operation of the unit the effect of pressure drop through the columns must not be overloosed. This is expecially important since it is the operating pressure at the top plus the pressure drop through the column which dotermines the pressure and temperature in the reboiler, where the largest amount of decomposition occurs. Therefore, for a given type of column, the pressure drop per foot of height will be the factor which determines the maximum permitted height and hence the number of columns required.

## (4) Holdup

Since the amount of material decomposed is directly proportional to the total holdup in the system, it is important that holdup be kept to a minimum. This can be accomplished by using as few towers as possible, thus reducing the number of reboilers, and by making the diameters of the towers small. Consideration of the fractionation requirements leads to the conclusion that the reflux ratio can be materially reduced as stripping progresses, without greatly increasing the plate requirements. This makes it possible to reduce successively the sizes of the towers, with the result that the tower containing the largest concentration of heavy polymer has the smallest holdup. Obviously, this is extremely effective in reducing decomposition of the neavy polymer.

Holdup is also an important factor in determining the time required to start up the plant, and in determining the time required for the system to come to equilibrium after a change in operating conditions.

## (5) Number of Columns

Since the unit is to be operated essentially as though it were a single distillation column, it is important that the number of columns used he kept to a simisum in order to keep the problem of control as simple as possible. However, the total number of plates required is

so firm in a space or particults and two five it also always percent the construction of the empty wholes a single of a notion in order to have the minimum number of a films, it is desired to empty column with a low one sure aron, low reliance of place with in the column, and a low reight equivalent to a theoretic injurie.

## (6) Survey of Design Factors

The factors involved in the really the be summarized us follows:

- i. The low relative volability requires the use of a large mater of lates and a high reflux ratio.
- consequention in a function of the pressure of operation, the pressure drop through the column, and the hoodup. For a siven radius rule, a decrease in pre-sure will reduce the decisionities rate, at this is behanced by the increased acklup due to the increased sive of the column. It is important that the pressure drop through the culture we kept low.
- class is also important in determining the time necessary to nature the columns to equilibrium.
- 4. In order to keep the number of towers to a minimus, at is injertant that the type of column chosen be one that computer with a low pressure drop, a low holdup, and a low height equivalent to a theoretical plate.(F.S.1.7.)

In selecting the type of column for the relection and recommendate that the desired encountries together with the mich reflex ratio payors a tower larger than twelve indices in itemster to the top of the obligant section and arbitably not as larger to a six inches in signeter at the product of the top accept the columns to the desired to the desired the factor of columns which are commercially available in this size.

## b. Fractionating Columns Considered

The types of frictionating columns considered for this project are tabulated in follows:

- (1) Eacty Column -Ested Wall
  Concentric tubes
- (2) Facked Column-formed racking
  "Heligrid"
  Spiral Screen
  Stadman
  Stadman-Weitkamp Modification
  Notating Column
- (3) Packed Column-humped Packing
  Berl Saddles
  Solid
  Gauze
  Haschig hings
  Wetal helices
- (4) Place Column—
  Pubble Cap
  Perforated Plate
- Since all of these columns are adequately described in the literature, no sitempt will be made to describe them here.

The empty columns were not considered practical for this job in view of the large number of tubes required, resulting in turn in an extremely difficult liquid distribution problem.

of the packed columns with formed packing, only the Stedman appeared to be worthy of consideration. Although the "Meligrid" packing is available commercially, it is not commonly constructed in sizes over 1". The spiral screen type is not available commercially, and in addition appears limited to columns of about 1" diameter. The rotating column did not appear desirable due to mechanical difficulties which could be anticipated due to moving parts.

of the packed columns with dusped packing, all of the types except the gauze berl saddles were available conmercially at the time of decision and were considered. Since the construction of the plant, gauze

Tound to compare favorably with Stedman packing. However, even at the present time facilities for production of saddles are limited and considerable time is required for their fabrication.

It was found that a tubble cap column of special construction had been developed by the M. W. Kellogs Company in which plate specings of 1-1/2 to 2 inches were used without excessive entrainment. This had been constructed in diameters as small as 6 inches, and therefore appeared worthy of careful consideration.

Examination of the characteristics of operation of perforated plate columns indicated that they aere inapplicable for the job. Although possessing the advantages of low pressure drop and low holdur, their disadvantage is an extremely rarrow operating range with the small plate spacing required for this 190. For example, it was found that the effect of decreasing the plate spacing was to decrease the operating range between the minimum vapor rate for good efficiency and the point at which entrainment became expessive. Extrapolation to a plate spacing of 2" indicated that this operating range became much too small for practical consideration.

The choice of columns for this project was thus narrowed down to packed columns such as Stedman, Berl Saddles, Maschig rings, and metal helices, and a bubble cap column of the Kellogg type.

Seri Saddles, about which very little was known at the time, showed that Stedman packing was outstanding in all three respects. Wetal helices give almost as low on H.E.T.P. as Stedman, but the pressure drop is nigher. Haschig rings are definitely inferior in all three respects, while Barl Saddles give several times the holdup and a very high b.E.T.P. It is probable that smaller Berl Saddles would show a lower H.E.T.P.

however, the holdup and pressure drop would then undoubtedly be higher.

The bubble caps show about twelve times the holdup of Stedman columns,
a higher pressure drop, and higher H.E.T.F.

## (5) Stedman Column Selected

The appeared evident that Stedman columns were outstandingly superior to all other types of columns which could be used for this project. This conclusion was verified by discussion with men familiar with all phases of high efficiency distillation. The above factors combined with the commercial availability of this type of packing led to the selection of Stedman columns for this project.

meshes per inch, using wire .009 inch in diameter. The cioth is punched, blanked and embossed to form sheets having a regular pattern of raised triangular pyramids, a pettern of holes located between the pyramids, and an upturned lip around the circumference. The sheets are placed one above the other so that the so-called "valleys" of one sheet are in contact with the granids on the sheet below, at which points the sheets are appropriately and together. The sheets are welded together in units containing loo sheets and measuring one foot in height.

The operation of the packing is as follows: The liquid flows along the wire cloth and scale the mesh, while the vapor passes opposed through the holes in the sheets. Good liquid distribution is maintained by the repeated division of liquid streams into three portions as they mass down the sides of the triangular pyramids and recombine with other streams in the valleys. Good vapor contact is assured by the fact that the hole of one sheet is always located directly below the apex of a pyramid in the sheet above.

The packing is fabricated in streular sizes up to 6 inch diameter, and in 6 inch equilateral triangles. Larger sizes are made

by combining train les into writing patterns to form bexagens and other shapes. For example, a 12 inch column is more of six triangular sections and is hexagenal in shape. In 12 inch column is more of thirteen triangular sections in the form of a hexagon having three twelve inch oldes and three six inch sides.

In determining the number and sizes of Stedman columns to be used on this project, I large number of combinations were considered and studies were made of each for different values of relative volatility of the two components to be fractionated. It appeared that with a value for the relative volatility of 1.00, accomplishment of the desired separation with six columns is somewhat uncertain due to the relatively high precours required, whereas with & equal 1.015, fewer then bix columns could protably be used. The combination decided upon was to consist of six columns, including two 18th hexagonal, two 12th hexagonal, and two the circular columns. This combination is the result of a compressive between theoretical considerations which indicate that six towers of progressively decreasing diameter would be most effective, and practical considerations, which indicate that the towers should all be the same size for interchangeability and maximum flexibility.

in order to offset major process uncertainties which existed at the time the design was established, particularly with respect to one and H.E.T.P., and in order to provide adequate spire facilities in the event of corrosion, leakings, or mechanical difficulties, it was decided to provide an extra column of each size, thus making a total of nine columns. Each column has a complete set of incurrents and muxiliary equipment and the piping is so manifolded that any or all of the columns can be used. The disdom of providing this spire equipment is evidenced by the fact that our one operation requires the entry sent of seven columns instead of the six calculated from the uncertain data

available at the time of design.

begun indicated a deleterinus effect of neight on the H.A.T.P. obtained with Stedman packing and hence in the final design of the unit, five redistributor plates were introducted in each column in order to insure that the required H.E.T.F. he obtained. The use of the redistributor plates limited the maximum neight of packing between plates to five feet and resulted in a total decrease in packed height of about 10%.

## (6) Construction Waterials

carly date, the materials of construction for this writ were selected on the basis of a limited amount of date and such other experience as could be brought to beer on the problem. Recent convercial experience with hydrofluoric acid slrylation plants had indicated that the presence of a small amount of solsture caused rapid corresion of either certon steel or stainless steel. Since polymer in the presence of moisture might hydrolyze to form hydrofluoric acid, and since moisture sight conceivably enter the system through an air, steam, or mater leak, it was decided to use monel wherever possible for a uipment which might be difficult to replace.

The towers are entirely monel except for carbon steel flanges. It was necessary to make the shell of monel in order to prevent fouling of the packing by scale, to insure maintenance of closely smachined telerances, and to climinate the possibility of accelerated corrosion rates due to the presence of two dissimilar metals. In the case of the flanges it was felt that the use of monel was not justified since the flanges could not be readily contacted by polymer, and since there was a large talerness of metal present in case the polymer did attack the flanges. Furthermore, a delay might be anticipated in obtaining monel 3" thick.

the reboilers and convenience are entirely of monel except for the reboiler shells. The use of forbon steel in this instance was based on the first that any moisture I aking into the system could remain in reboiler for only a negligible amount of time, since the boiling point of water is considerably below that of polymer.

The disparages for the pusps are made of monel, while the obeck values are of stainless steel. The problems values have forged steel bodies with a nel and copper trim. All other pieces of equipment, including coolers, draws, and biping, could be readily replaced and hence were made of carbon steel. Furthermore, it was felt that say necessary changes in this equipment could be more readily ande in the field with ourbon steel, due to familiarity with its selding characteristics.

g.s.

: 17

Experimental work at Sak Laboratories later should stainless atcel to be as good as more! When tested with polymer slower or "lin polymer in the presence of small ascumts of amisture. However, with polymer in the presence of steam, stainless steel showed the rapid corresion rate which had been anticipated, whereas much we array alightly affected. Furthermore, investigation of the welding and another pharmacteristics of various stainless steels showed them to be inferior to monel, since stainless steels showed them to be inferior to monel, since stainless steels which were readily welded were difficult to machine and those which were stally machined wore difficult to read. Hence it was found desirable to use monel in spite of procurement difficulties which were encountered.

Poster bheeler Corp. in the productment of monel from international Nickel and in the clicking of orders with fabricators who were experienced in the workings of this material. Expeniting assistance was rendered by the hashington lisinon Office, Endison Equare are: Office, Chicago Area Office, and the standard Cli Company with the result that these difficulties were resolved. In important contribution to the early delivery of these essential monel parts was the cooperation of various proval ordered plants.

in the wachining of the topor opetions.

## 4. Initial operations

In order to meet early delivery tonedules, in attempt was made to place each unit of the plant in production at Past as its assertly was completed. without the deliberate and extensive testing procedure which would precede the operation of such a novel plant under normal conditions. As might be expected in an attacpt to go from incomplete lators very experimental work to production without intermediate trials on a pilot scale, unforeseen difficulties were encountered. Chief of these difficulties were those related to leaks and an entirely new system of lear detection was developed. By direct comparison at the plant it was found that this leak detection who required to find leaks which could not be detected by the nellum mass spectrograph "smiffer", the most exhaustive lesk detecting instrument known at present. Another major difficulty was encountered in the unsatisfactory performance of the pumps under operating conditions. The comps were tested prior to installation but these tests were interrupted and, hance, incomplete, due to the necessity for incorporating the pumps in the operating unit. Standard Cil Company immediately redesigned the pump and the vendor fabricated new pumps in accordance with this design. The new design purms have given satisfactory service.

Euring the leak testing procedure, wercapy was introduced inadvertently into the system from the pressure relief chambers. These pressure relief chambers had been constructed so that an external pressure greater than atmospheric was required to cause the flow of moreury into the system. However, an extraordinary occurrence of events such as emulaification, loss of mercury by flowing outward, and "rocking" did result in mercury contamination of the operating system. Suntrary to Judianed literature and the experience of all concerned, including the operators, the sulface of the research facilities at SAE, and the verders of somel; the moreury did attack the monel under the peculiar conditions

Carrie

of operation and brought should structured (allure of the component parts of the system. If was later ecofirmed by Laboratory demonstration that under a number of unusual conditions which must be present at the same time, herebry dose so attack some netal.

## 5. Supplementary Flant Considered

Collectly because of the structural failure of the first plant but also from consideration of the fact that the first plant had been built without a pilot plant and subsequent experience had shown a large number of possible improvements in design, the contractor proposed that a new plant be designed and constructed in order to insure satisfactory production. It was proposed to construct this new plant of three equivant rather than six in order to decrease the number or valves and heat exchangers which appeared to be the fock of isake and, thus, the chief causes of fundamental difficulties. The reduction in the number of reboilers would also be advantageous in view of the unsupertedly large decomposition which had been experienced in the repoilers. The material of construction was to be carbon steel, which, in spite of its faster correction, did not reset with mercury under the unusual conditions which alight occur signin through accident.

After consideration by higher authority, it was decided to proceed
with a second, completely new, fractionating plant embodying the new design
features. In the meantime, the first plant was to engage is a testing program
to determine the best conditions of operation in order that these features
might be incorporated in the design of the accord plant. The placement
of orders for material and other preparations for the new plant were to
proceed mithout delay. In order to save the time necessary for the
preparation of a foundation adequate to support the required abrupture,
the Standard Oil Company agreed to the use of the foundation of an existing
but abandoned structure, identified so No. 5 Boil r House. It was

necessary to raze the walls of this existing structure to a large extent since they would constitute a nazard to personnel working in the vicinity. Itsactiate action was taken in the praparation of the site and the placing of orders for new packing and column sections. Ine packing and column sections were to be identical with the corresponding portions of the existing plant so that they would serve as mutual spere parts in the event of replacement if such became necessary.

while proceeding with the experimentation on the original plant, the contractor discovered (a) that mercury could be removed from the system and the structural failures almost completely stopped, (b) that leaks could be controlled, (c) that, in spite of failure to perform in accordance with predictions from laboratory data and design calculations, the plant was operable, at least in a slow and onerous batch fashion. Accordingly, a quantity of his material and later 80% material was prepared by a variety of batch and semi-continuous operations and delivered to the government for further processing and final utilization by the requesting agency.

about 9 January 1945, the government reconsidered and instructed the contractor to proceed no further with the producement and erection of the second plant, but instead to produce to the best of their ability upon existing facilities and to utilize such equipment as was already produced to repair and maintain the present facility in an operating condition. By testing and adjusting the various units of the plant, the contractor has brought them, one after another, into integrated operation so that successful continuous operation has been attained. Despite the fact that laboratory predictions were not realized and design efficiency as not possible, the skillful operation of the contractor has resulted in the production of a quantity of 80% enriched material, and more recently,

in the production of more than 90% material upon a continuous and uninterproced basis. Operating conditions are still being improved and the desired concentration of 95% is now forthcoming.

## 6. Future Possibilities

The future operation of the plant is indeterminate. For reasons of security, the exact operation and need underlying this procurement requirement is undisclosed. The contract specifies production at a certain rate for the duration of the war and six months thereafter. In the event that there is a requirement only for a specific quantity of this material. its unique nuclear properties make it useful for other proposes which may justify the operation of the plant for additional quantities. One of the most universal of these additional uses is the employment in membron detecting instruments. Already, laboratories which have learned of the existence of this material have made request for quantities of the material for such a purpose. A relatively small portion of the production is sufficient to satisfy these needs. However, since the process saterial is extremely corrosive, it is probable that a prolonged period of idleness would render the plant inoperable. It is doubtful that it will ever be economically feasible to operate this plant or another for the sole purpose of supplying this material for instruments except during the current period of operations.

In addition to potential operations utilizing the process saterial for which it was designed, the plant represents a completely astounding fractionating instrument. Hence, although its design may render it inefficient for practical production purposes, it is a very valuable instrument upon which to attempt the fractionation of other isotopes by distillation method. If a volatile compound of uranium could be discovered in which the two isotopes had a different relative volatility, the relatively

simple distillation recess could be used to displace the intricate and curdersome cathods for in use for the separation of the isotopes of this element. Not only would the design features of the present plant be incorrect for practical use in separation of brankow isotopes, but is is likely that the previous use with boron compounds would remar the isotopes of brankow produced unsuitable for nuclear purposes. The actual resthility of the separation process, however, could be demonstrated by means of the powerful tool which exists in the plant. Although the existence of a suitable compound of brankow is not known at this time, it is entirely conceivable that such a compound may be discovered.

timewise, it is conceivable that needs will arise for isotopes of other elements and that volatile compounds of these elements any exist in which the isotopes differ sufficiently in volatility that they may be separated by distribution. The present facility, in all probability, is not so designed and constructed that an efficient separation right be occumplished but it does represent a very powerful machine which magnitude emilyed for experimentation in order to determine the data from which a production facility hight be designed and erected.

29 April 1944

Subjects Vitamin.

EIDM CGD-4 S10-18

Dr. J. R. Oppenheimer, P. O. Box 1663, Santa Fe, New Mexico. Tos

- 1. Confirming telephone conversation between Dr. Oppenheimer and Captain Chapmen of this office of 28 April 1944 and teletype of 29 April 1944, the immediate status of the vitamin project is submitted for your information.
- 2. The vitamin facility under construction and to be operated by the Standard Oil Company (Indiana) consists of 18 monel metal towers filled with Steadman Packing. In detail, there are 3 - 6" cylindrical towers and 3 - 12" hexagonal towers and 3 - 18" hexagonal towers. The design capacity of the equipment is such as to provide 600 grams of Boron per day in the form of the tri-fluoride dimethyl ether complex and of 95% B10 isotopic concentration. Initial delivery date as specified by the contract was 2 June 1944 but due to difficulties in obtaining monel metal, this initial delivery date had been changed to 3 July 1944.
- 3. Delivery of monel metal was later than in accordance with the established schedule. When it was received, it was found to be in an unsuitable form due to scale and irregular surfaces and further delay was incurred in preparing the plate for fabrication. As a result of these delays, the completion dates of the fabricated sections of the hexagonal towers have been placed at around 60 days from 8 May 1944. There are two authentic but conflicting statements with regard to the date on which the sections can be completed. The exact delay can not be determined at this time. Efforts are being made to place part of the tower machining in other shops in order to expedite final completion date of the entire facility.
- 4. The cylindrical columns, due to design and size offer smaller machining problems and are expected to be complete not much later than schedule. By rescheduling the hexagonal columns, it is anticipated that at least 2 of the 12" columns can be completed prior to the completion of the 3 -6" columns. Preliminary engineering studies have indicated that with these 5 columns a production rate approximately 75% of the contracted rate and of specification concentration can be attained. The contractor has been instructed to proceed with the fabrication and erection on a schedule which will allow the initial production date to be realized at this reduced rate. Expediting and completion of the entire facility will be continued with no dimunition of intensity.

- 5. The Chicago Office has been informed informally and unofficially that a redetermination of alpha allows the prediction that this facility will be able to produce the BlO complex at a rate greatly in excess of that specified in the contract. It is, therefore, believed that any loss in accumulative production sustained by this reduced operation can be regained in a short period of time after the entire facility is completed and in operation.
- 6. It is contemplated that delivery of the complex will be initiated at a rate of 450 grams a day based upon BlO content on 3 July. This material will be delivered to the Madison Square Area for reduction to the crystalline material in a facility under the supervision of that office.

1458

Following the initiation of the project under locations to.

1-418-eng-41, leted Leaguer 2, 1945, a fractionating will for the production of heavy polymer was designed, constructed, and successfully operated for a pariod of 14 months. During the pariod of operation a total of 700 gallens of heavy polymer was produced. In accordance with instructions received from the U.S. Engineer Office the unit was shut form on February 4, 1946 and was placed in a tend-by condition. In accordance with an amendment to the contract, inted February 1, 1848, the unit will be maintained in a tend-by condition until lanuary 1, 1848 units the Engineer Office directs its earlier disposal.

Process lealing of the fractionating writ was begun u. lecomber 6, 1948 and shortly thereafter a sub-contract was entered into with the Postor Published Corporation for the design and prection of the pleat. After madrous difficulties were encountered, many of which required extensive modifications of the plant, successful operation was attained shout one year from the start of the project. During the last part of the first year. t second unit was designed and plans were made for its installation. However, this unit was abandoned before its erection was started how it became apparent that the first unit could be made to operate properly. Trubles which were encountered in the prootion and operation of the first unit included difficulties in procuring and fabricating Money, mechanism failure of Monel rolumn sections and heat exchangers, and difficulties associated with pumps, velves, and column packings. These difficulties are discussed in detail in Report No. A-2570 Issued by the Standard Oil Company under date of July 25, 1946 and entitled. "Construction, Operation, and Maintenance of a Polymer Fractionation Units. This report also contains a number of "ocormonded changes in design which should be considered should a similar unit be constructed in the future. Completion dates for the principal places of the project work are shown below

Design of resjor equipment completed	March 1, 1944
Proparation of pilot plant site and installation of offices and laboratory completed	March 1, 1944
Prection of pilot plant facilities completed and proliminary attempts at operation begun	July 22, 1944
Mirst successful cross-flow operation established	Normaber 28, 1944
Production of 80 per cent heavy polymer attained	обликту 5, 1945
Production of 25 per cent heavy polymer attained	March 50, 1946
[perations terminated]	Formary 4, 1946

Puring the period of successful operation, product was mithdrawn from the unit more than 96 per cent of the elepsed time. The material produced by the unit consisted of 90 gallons of 60 to 90 per cent heavy polymer, 95 gallons of 90 to 96 per cent heavy polymer, and 56% callons of material having a heavy polymer concentration of over 95 per cent. Here detailed information regarding the material produced is shown in Table I.

Total Foster Wheeler Subcontract Evnence	91 500 000 PA

Above figures subject to final sudit.

A number of contributions were sade to the fund on I knowledgeof the of listry of the process during a graphed of recourch and devolope. ment under tak in to aliminate difficulties which occurred both prior to and dering the period of successful operation. These contributions were concerned with the mesimplem of the resorter between polycer and water, the equilibrie existing to wrem polymer and its decomposition products, and the isotopic explange of element between polymor and a mapber of other compounds.

Chemical engineering information of importance to industry was obtained on the performance of Stadman and schahon types of column proking. In addition, information of considerable interest was obtained on not had of detecting lasks in process equipment and on the use of disphragm pumps for handling liquids under diffic it operating conditions.

Work of particular importance to the project was that done on the improvement and development of inelytical methods for determining the quality of polymer. This included the use of the counter method for determining the consentration of heavy element in polymer and the development of the emphance settled for prejaring samples for the "Ill" morelytical machine. Complete dutails of all its research and development contributions ende during the property included in the reports thich were issued in connection with the work. These reports are listed in Table II. Included is much inflammedian on the construction and performance of the plant southwest. in addition to details of the cirtly design and domelogacht work.

The ork of the project so tarried out or a large number of -mrever like lonnormy in the training bard local and remember to the first state of the f the project situate are listed in Coll. Table SV and listed in the of the persons, not heaveling the entering and the course of the property of the same of the course o in a contract. This list includes when the desimilarly have the of the project as well entires who may have been and to correctly ryrow the objective from the information mass available to them.

All expenditures involved in the work are presented in detail in is shown, the total amounted to \$2,009,868.88. This emount was the sum sound for all work done up to and including July 31, 1946.

Standard Oil Company of Indiana.

and for services in connection with the close-out of operations, all as required or approved by the Contracting Officer. In conformity with current negotiations, it is proposed that you maintain process equipment in No. 4 Process Laboratory in stand-by condition and store Government property on a mutually agreeable fixed-price basis to be covered by a supplemental agreement to this contract.

Receipt is acknowledged of your break-down of proposed fixedprice for stand-by and storage. It is requested that you furnish for approval of the Contracting Officer an estimate of all costs, except for storage and stand-by, that may be incurred in connection with the above directions.

Acknowledgment of receipt of this letter is requested.

Very truly yours,

/s/ A. Tammaro
A. TAMMARO,
Lt. Col., Corps of Engineers,
Contracting Officer.

INW-320-b -7419-eng-41 1153

8 March 1946

Standard Oil Company of Indiana, 910 S. Hichigan Avenue, Chicago, Illincis.

Attention: Mr. J. K. Roberts.

### Gentlemen:

Reference is ade to your Contract No. -7418-eng-41, dated 2 December 1743, for the design, construction, installation and operation of facilities for the production of X Project.

Confirming telegram dated 1 February 1946, you are directed to cease operation of the facilities effective 3 a.m., 4 February 1'46, except for final processing of such material then in process which in your judgment is economical. You are further directed as follows:

- 1. Promptly wash out the plant and place it in stand-by condition.
- 2. Dispose of product as directed by Contracting Officer.
- 3. Furnish a report summarizing your activities, findings, and conclusions and such other reports as directed by the Contracting Officer.
- 4. In conformity with Argicle XII of the contract dispose of all Government property determined by the Contracting Officer to be surplus.
- 5. Place all other Government property in your No. 3 Boiler House and securely lock such premises as directed by Contracting Officer.

Reimbursement will not be made to your for expenses incurred after 8 a.m., 4 February 1946, unless subsequently directed to resume production, except for the work above-mentioned and except for such expenses as may be necessary for the protection of Government property
